Reflection

The Unity prototype for *Jay A Career* was designed to translate the proposed game concept into a small and achievable playable environment.

The concept focuses on a daily gameplay loop in which Jay prepares for a delivery, travels to a customer, negotiates a simple deal, returns to the workspace, cleans the environment and progresses to the next day.

The prototype demonstrates the Unity skills required by the assignment, including GameObjects, Transform manipulation, materials, textures, scene construction and Prefabs. The project uses the Universal Render Pipeline and does not use Cinemachine, following the assignment requirements.

The environment contains more than the required 20 GameObjects/models or placeholders. These include the player, characters, laboratory furniture, equipment, storage objects, vehicles, environmental objects and architectural elements.

The prototype also uses at least 20 distinct materials/textures, including a dedicated floor material. These materials help distinguish different objects and areas of the environment.

Prefabs are used for repeated objects such as tables, chairs, shelves, barrels, crates and environmental props. This allows objects to be reused efficiently while keeping the Unity project organized.

The prototype intentionally avoids complex systems such as multiplayer, advanced artificial intelligence, combat and a large open world. This allows the project to concentrate on the core concept and the Unity skills required for the assignment.

The final prototype connects directly to the Game Concept Document because the environment, objects and interactions were selected to support Jay's daily routine and progression.

Overall, the prototype demonstrates how the original *Jay A Career* concept can be transformed from a written game idea into a functional Unity environment using the fundamental techniques introduced in the practical laboratory.
